Overview

Introduction

- ▶ Galileo 5+6 redshift test

Redshift evaluation

- ▶ redshift parameter α
- ▶ clock residuals

Models

- ▶ Solar radiation pressure
- ▶ Galileo FE model

First results

- ▶ SRP parametric analysis
- ▶ SRP influence on redshift

Conclusion and Outlook

Galileo system

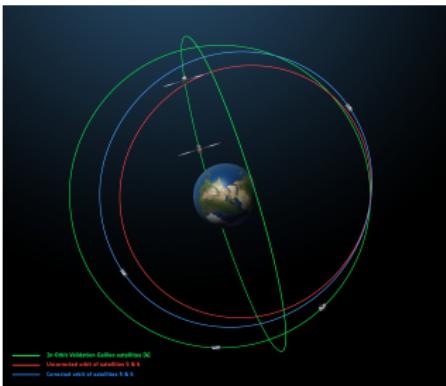

- ▶ European Positioning System (Joint EU/ESA project and several non-EU states),
- ▶ Project Start 2003,
- ▶ A total of 30 Satellites in circular orbits at 23260 km,
- ▶ Walker-constellation (56° :27/3/1),
- ▶ IOV Satellites manufactured by Airbus, FOC Satellites manufactured by OHB,
- ▶ Currently 14 FOC in orbit, completion planned in 2018.

Galileo FOC geometry, Source:ESA

Galileo launch anomaly

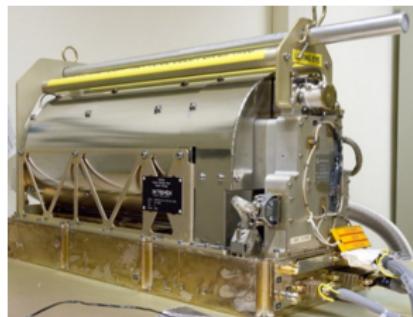

Galileo 5+6 Orbits, Source:ESA

	GSAT-5	GSAT-6
a	27978 km	27978 km
e	0.15601	0.15167
i	49.775°	49.874°
h_a	25818 km	25848 km
h_p	17240 km	17220 km
T	12.9367 h	12.9366 h

- ▶ Launch anomaly during Galileo 5+6 launch,
- ▶ Valve failure in Fregat upper stage,
- ▶ Consequence: Non-nominal elliptic orbit,
- ▶ Satellites flying through van-Allen belts,
- ▶ Available fuel used to reduce eccentricity and to increase orbit altitude.
- ▶ But: final orbits of both satellites are still elliptic!

High precision clock in space

- ▶ Satellite bus is equipped with PHM and RAFS clocks,
- ▶ Stability w.r.t. orbital period:
 $\sigma_{y,PHM} = 3 \cdot 10^{-15}$, $\sigma_{y,RAFS} = 2 \cdot 10^{-14}$
- ▶ Orbits are still elliptic → high precision clocks in a changing gravitational potential!
- ▶ Perfect conditions for a test of the gravitational redshift!

Redshift parameter α

A clock's ticking rate slows down if brought closer to a massive object.
The resulting redshift can be tested with test parameter α :

$$\frac{\Delta\nu}{\nu} = -(1 - \alpha) \frac{\Delta U}{c^2} .$$

The most accurate test of α has been conducted with GPA (hydrogen maser on a sounding rocket) : $\alpha < 1.4 \cdot 10^{-4}$,

Vessot et al., Phys. Rev. Lett. 45 (1980)

Redshift model in time domain

Leading order relativistic effect:

$$\Delta t = \int \left(\underbrace{1 - \frac{(V - \Phi_0)}{c^2}}_{\text{Grav. Redshift}} + \underbrace{\frac{v^2}{2c^2}}_{\text{Quadr. Doppler}} \right) d\tau.$$

Influence of eccentricity:

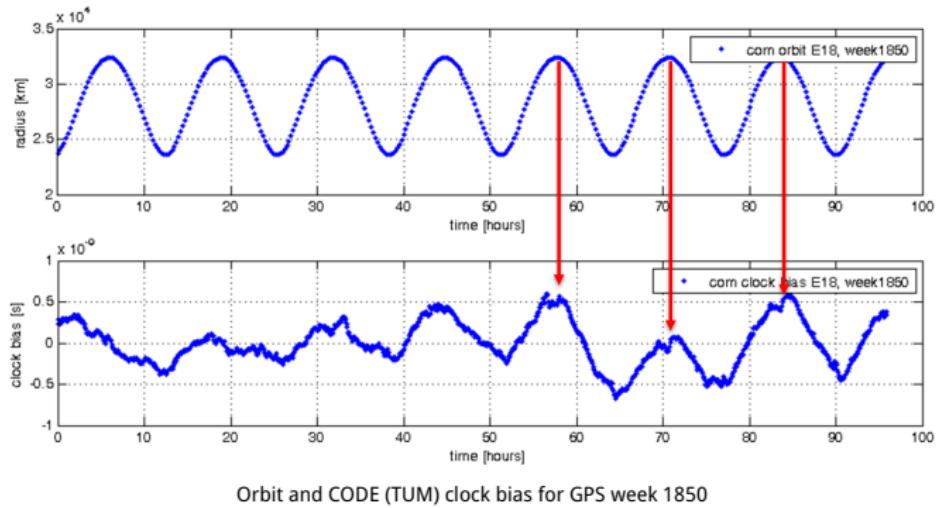

$$\Delta t = \int \left(\frac{3GM_E}{2ac^2} + \frac{\Phi_0}{c^2} - \underbrace{\frac{2GM_E}{c^2} \left(\frac{1}{a} - \frac{1}{r} \right)}_{\Delta t_r = \frac{2\sqrt{GM_E a}}{c^2} e \sin E + \text{const.}} \right) d\tau.$$

Practical implementation:

$$\Delta t_r = \frac{\vec{v} \cdot \vec{r}}{c^2}.$$

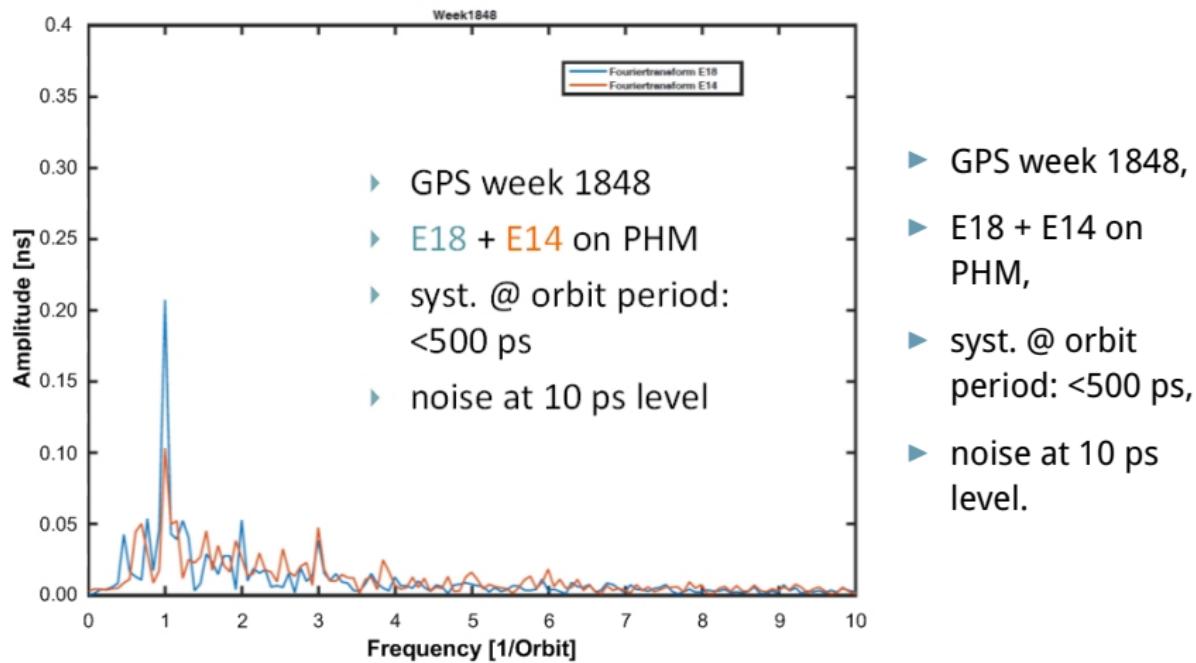

Clock residuals

Possible cause of systematic effects:

- ▶ Direct systematics on satellite clock: Temperature effects / Magnetic fields,
- ▶ Indirect systematics on orbit/clock solution: **SRP mismodelling** / Attitude effects,
- ▶ Systematics on ground clocks ?

Clock residuals

Solar radiation pressure model

Photon momentum:

$$\begin{aligned} E &= \sqrt{(m_0 c^2)^2 + (|\vec{p}_{\text{Ph}}| c)^2} \\ \rightarrow E_{\text{Ph}} &= |\vec{p}_{\text{Ph}}| c \text{ mit } E_{\text{Ph}} = h \nu_{\text{Ph}} . \end{aligned}$$

Momentum exchange when absorbing photons:

$$\frac{d|\vec{p}|}{dt} = \frac{h \nu_{\text{Ph}} dN}{c dt} = |\vec{F}_{\text{TRP}}| = \frac{P}{c} .$$

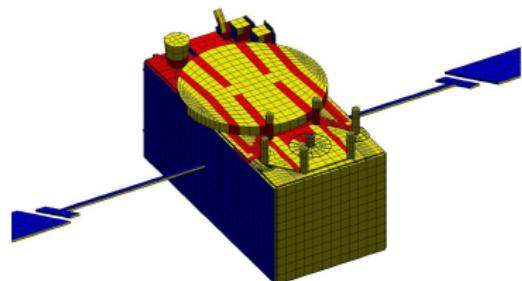

Received Solar Power:

$$P_{\text{Sat}}(r) = \frac{P_{\odot, 1AU}}{r^2} \alpha A_{\text{Sat}} .$$

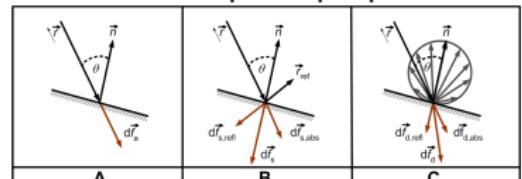

Resulting SRP force per surface element:

$$\begin{aligned} d\vec{f}_{\text{res}} &= d\vec{f}_a + d\vec{f}_s + d\vec{f}_d \\ &= \frac{-P_{\text{inc}} \cos \theta dA}{c} [(1 - \gamma_s) \vec{r} + 2(\gamma_s \cos \theta + \frac{1}{3} \gamma_d) \vec{n}] . \end{aligned}$$

Implementation of shadowing:

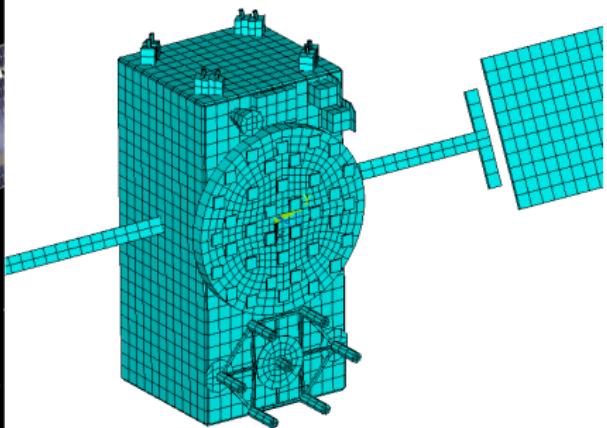

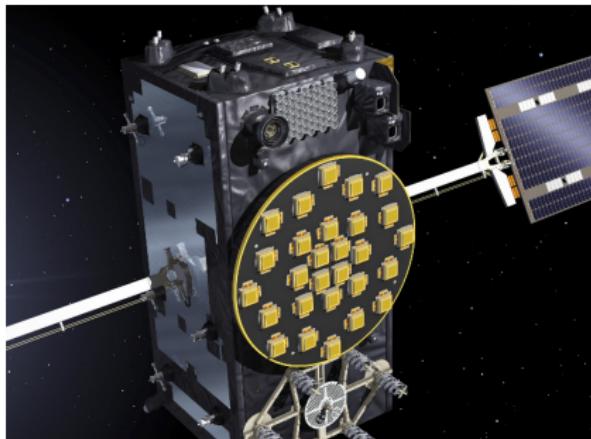

Treatment of optical properties:

A: Absorption, B: Spec. Reflection, C: Diff. Reflection

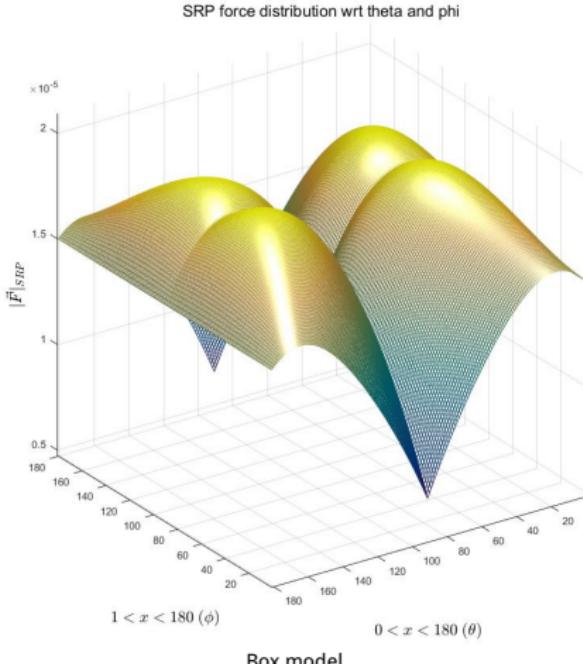

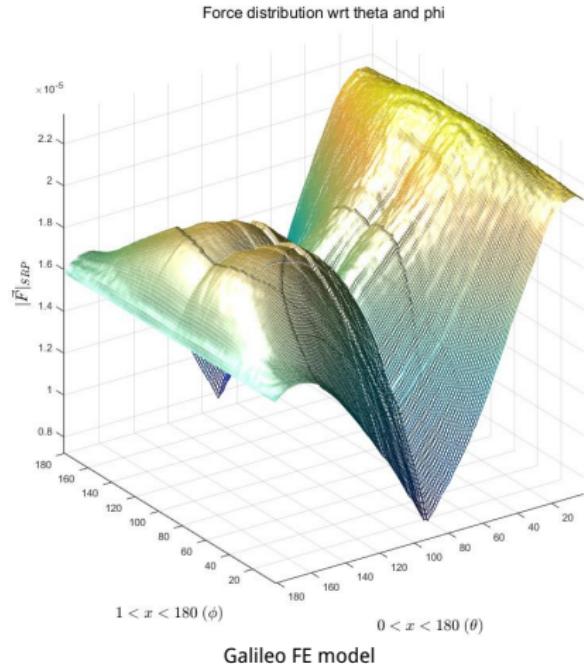

Galileo FE model

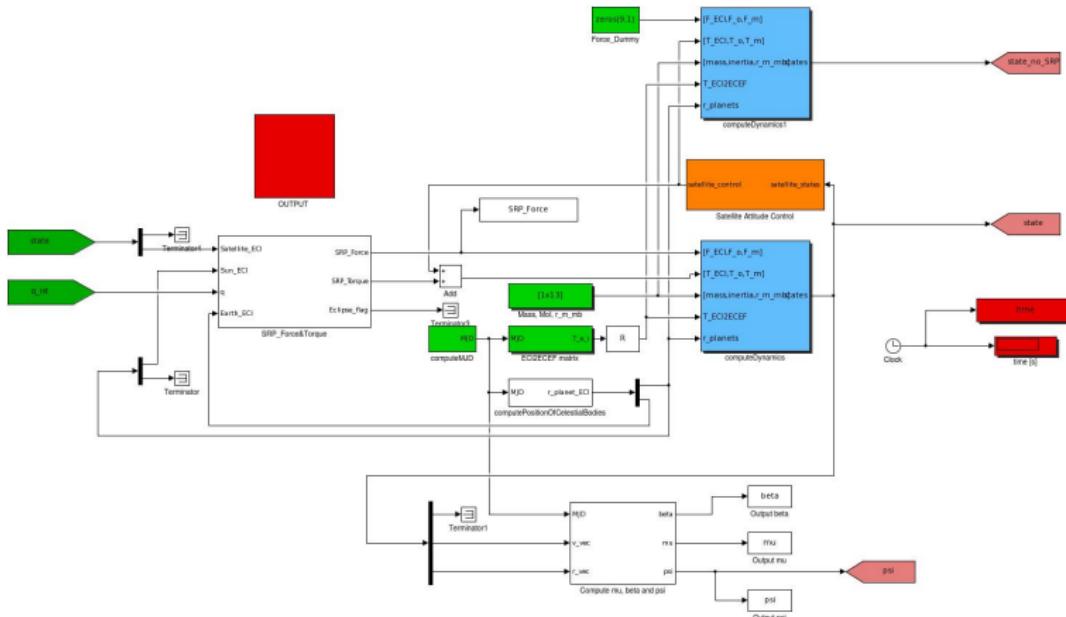

Comparison between real satellite and FE model

- ▶ Different optical properties for each surface cell,
- ▶ Orbital state and attitude from numerical orbit/attitude simulation.

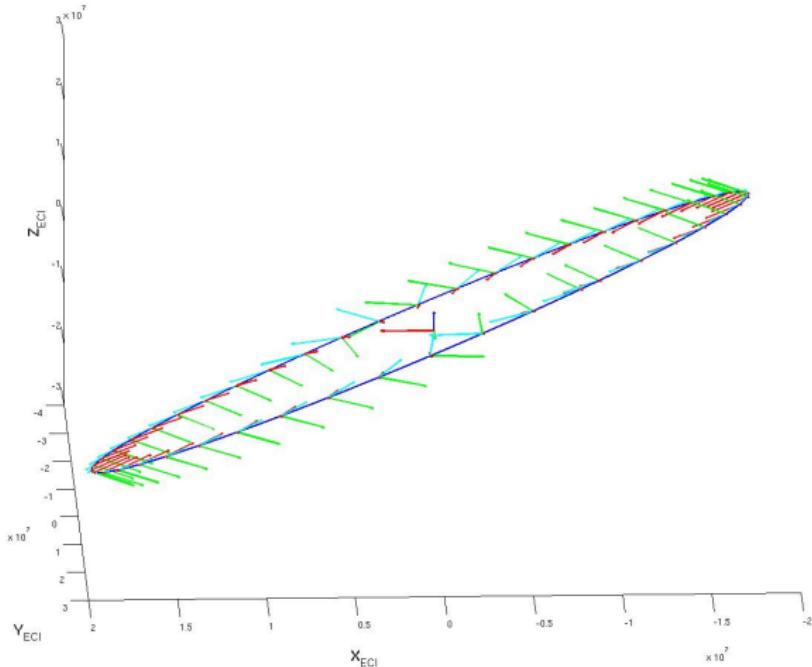

Parametric analysis: Solar incidence angle

Orbit model

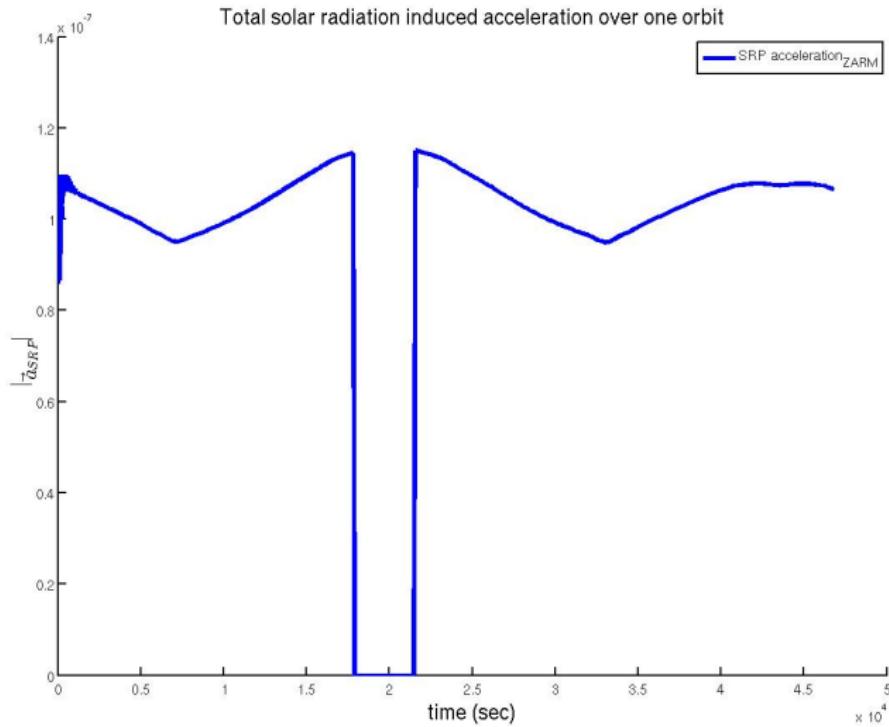

Orbit model

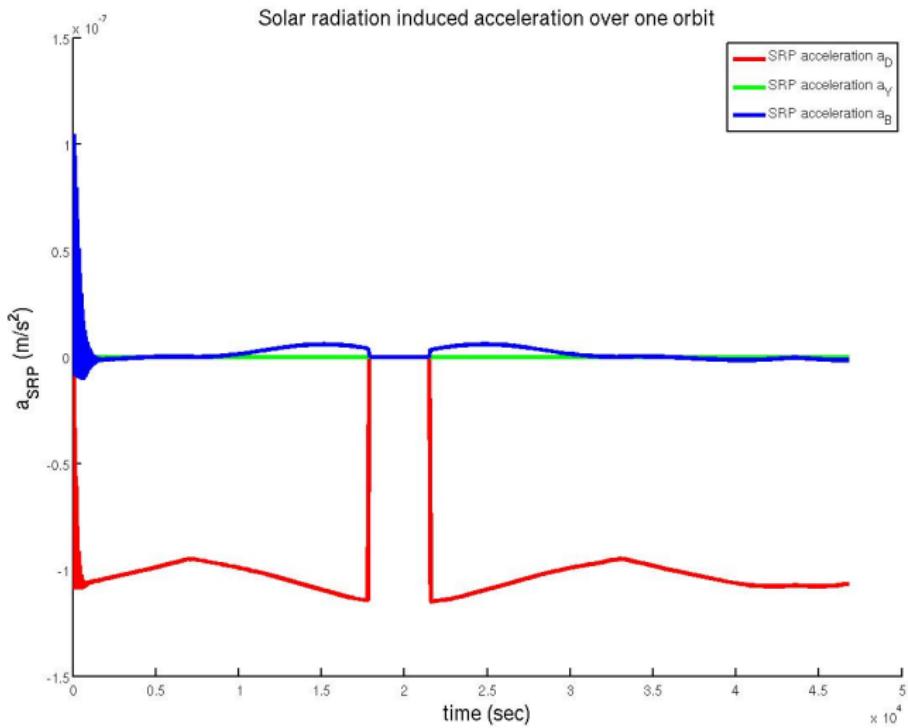

Simulated satellite attitude (yaw-steering) and trajectory

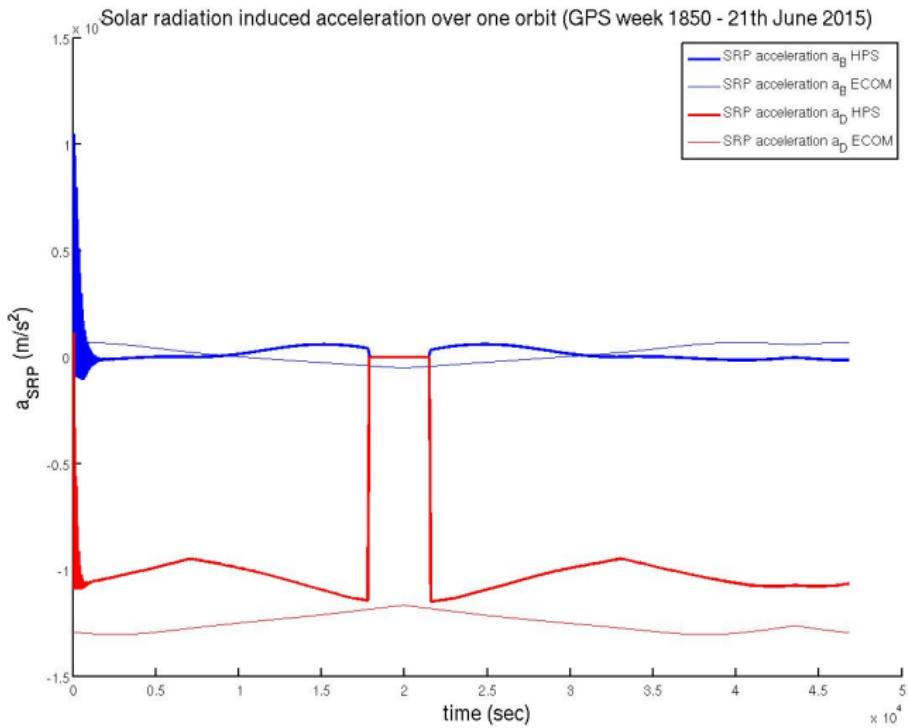

First SRP results

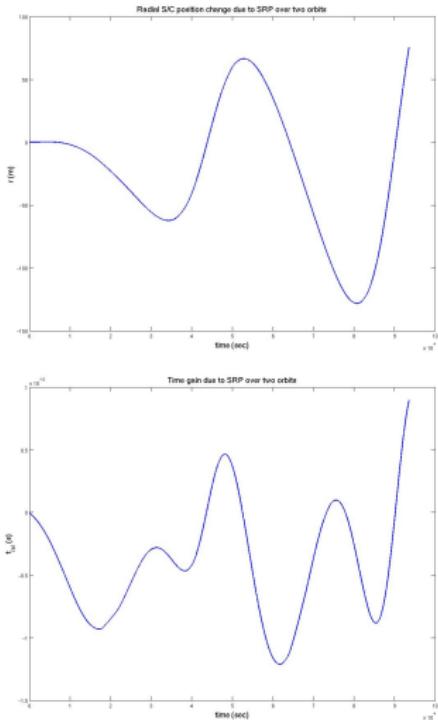

First SRP results

First SRP results

Predicted Redshift due to SRP

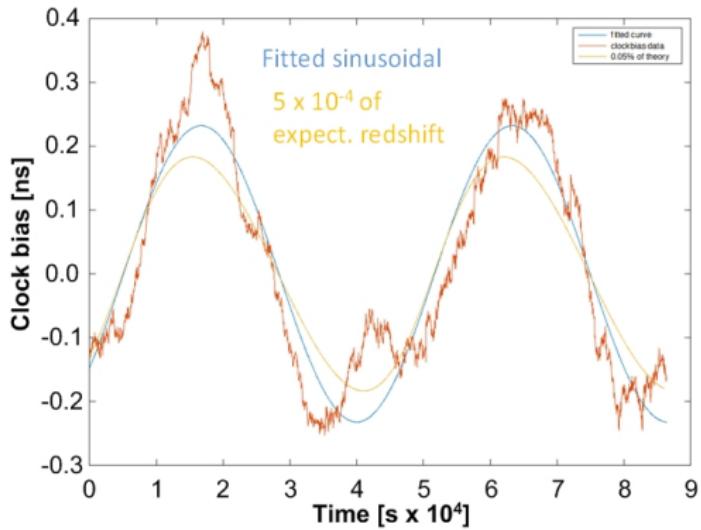

- ▶ Radial Position change growing with each orbit,
- ▶ Observed residuals correspond to about 100 orbits with SRP,
- ▶ Leads to modulation of clock residuals at orbit frequency,
- ▶ Causes secondary frequencies at satellite rate and 1 year.

Conclusion

- ▶ A priori model for Solar radiation pressure,
- ▶ Input: Satellite geometry, materials, trajectory, attitude,
- ▶ Better accuracy with respect to Box-and-Wing, Cannonball, ECOM,
- ▶ Self-Shadowing and Reflection included,
- ▶ Clock residuals at orbit frequency strongly suggests SRP influence on redshift,
- ▶ Total improvement may lead to a better α compared to GPA.

Outlook

- ▶ Reduction of residuals by improved SRP model,
- ▶ Improvement of orbit determination by SLR campaign,
